

1     **ABSTRACT OF THE DISCLOSURE**

2           A spinal expanding apparatus includes multiple supports extendable out of  
3     passages in a body and a bolt movably received in the body. The bolt has multiple  
4     grooves in an outer periphery of the bolt to correspond to bottom conical heads of the  
5     supports. Therefore, advancement of the bolt is able to force the supports to  
6     simultaneously extend out of the passages of the body. Each of the supports has a  
7     travelling distance the same as the others so that two adjacent spines are evenly  
8     separated.
